

The specific scientific field that studies the resurrection and botany of these ancient seeds is **archaeobotany** (also known as **paleoethnobotany**).

This discipline sits at the intersection of archaeology and botany, focusing on how human-plant relationships evolved through the recovery and analysis of ancient plant remains.

Several other closely related scientific fields collaborate on this specific research:

Primary and Specialized Fields

- **Archaeobotany / Paleoethnobotany:** Studies ancient seeds, pollen, and plant genetics to reconstruct past environments, diets, and agricultural practices.
- **Lazarus Botany / Resurrection Botany:** A highly specialized subfield of plant science dedicated entirely to reviving extinct or millennia-old plant species from dormant seeds or tissues.
- **Archaeogenetics:** Uses modern DNA sequencing techniques to analyze ancient genetic material, mapping out how ancient crops were domesticated and traded.

Supporting Disciplines

- **Horticulture and Agronomy:** Focuses on the practical cultivation, soil science, hydration, and cross-pollination techniques needed to keep the revived plants alive and producing fruit.
- **Plant Physiology:** Investigates the cellular mechanics of seed dormancy, examining how a seed's embryo can survive for 2,000 years without drying out completely or rotting.

If you are interested, I can share details about **other ancient plants** that archaeobotanists have successfully resurrected, or I can break down the **lab equipment and techniques** they use to extract 2,000-year-old DNA.
